

## Topics since the third exam's review sheet

**Note:** The final exam covers topics from all of our review sheets for the semester.

**Work**

In physics, one studies the behavior of objects when acted upon by various *forces*. Newton's Laws provide the basic connection between a force acting on an object and the effect it has on its motion:

$$F = ma ; \quad \text{Force} = \text{mass} \times \text{acceleration}$$

Two basic quantities to compute, when you know the force, are *impulse* and *work*.

Impulse measures the effect of a force over time. If a constant force  $F$  is applied to an object, over a time interval of length  $T$ , then the impulse imparted to the object is  $\text{Impulse} = J = F \cdot T$ . But typically the force being applied will not be constant. Then we do what we usually do: look at the impulse generated by the force over a short time interval (where the force is effectively constant), and add up the impulses imparted over all of these little intervals.

$J \approx \sum F(t_i) \Delta t$ , which looks suspiciously like an integral. So we define  $J = \int_0^T F(t) dt$

But in classical physics, where  $F(t) = m \cdot a(t) = m \cdot x''(t)$ , if we can treat  $m$  as a constant, then we can integrate  $F$ , so

$$J = m \cdot x'(T) - m \cdot x'(0) = m \cdot v(T) - m \cdot v(0)$$

is the change of momentum of the object.

In physics, *work* represents force being applied across a distance. If a constant force  $F$  is applied to an object, which moves the object a distance  $D$ , then the work done on the object is  $W = F \cdot D$ . Again, if the force applied across this distance is not constant, then we interpret work, instead, as an integral, by cutting the distance covered into small pieces of length  $\delta x$ :

$$W \approx \sum F(x_i) \Delta x, \text{ so } W = \int_0^D F(x) dx$$

An interesting application of these ideas comes when trying to compute the amount of work necessary to pump out a tank of some known shape. If the tank has height  $D$  (we will think of the top of the tank as being at  $x = D$  and the bottom being at  $x = 0$ ), and at height  $x$  our cross-section of the tank has area  $A(x)$ , then if (as when we computed volume) we think of the fluid in the tank as being a stack of cylinders with height  $\Delta x$ , the work necessary to lift the slice at height  $x$  to the top of the tank will be

$$W = (\text{force})(\text{distance}) = (m \cdot g) \cdot (D - x) = ((A(x) \cdot \Delta x)\rho g) \cdot (D - x)$$

where  $\rho$  is the density of the fluid,  $m = \text{mass} = (\text{volume})(\text{density})$ , and  $g$  is the acceleration due to gravity (which provides the force we need to overcome to push the fluid up out of the tank), and  $D - x$  is the distance that the slice must be lifted. Therefore, the work done to empty the tank is approximated by a sum of such quantities, which in turn models a definite integral; the work done in emptying the tank is

$$W = \rho g \int_0^D (D - x)A(x) dx$$

In English units,  $\rho g$  is typically reported in pounds per cubic foot,  $A(x) dx$  has units of cubic feet, and  $D - x$  is feet, so the integral has units of foot-pounds.

## Math 107: a checklist of topics encountered

### Techniques of integration

- $u$ -Substitution
- Integration by Parts
- Trigonometric Substitution
- Trigonometric Integrals
  - reduction formulas
- Partial Fractions
- Numerical Integration
  - trapezoid rule, error estimates
- Improper Integrals
  - convergence, (limit) comparison theorem

### Applications of Integration

- Volume by Slicing
- Volume by Cylindrical Shells
- Arclength
- Exponential Growth and Decay
- Work

### Sequences and Series

- $n$ -th Term Test
- Geometric Series
  - exact calculation of sums
- Comparison/Limit Comparison Tests
- Integral Test
- Ratio(n) and Root Tests
- Absolute and Conditional Convergence
  - alternating series test, remainder estimate
- Power Series
  - radius of convergence, term-by-term differentiation and integration
- Taylor Series
  - Taylor's Theorem, remainder estimates

### Polar Coordinates

- Polar coordinates vs. Cartesian coordinates
- Polar Curves
  - slopes of tangents
  - area enclosed by curve
  - arclength

### Vectors

- Coordinate representation, Length
- Angle, Dot product
  - orthogonal projection
- Lines in 3-dimensional space
  - distance from a point to a line

### Vector-valued Functions

- Parametrized curves in space
- Differentiation and Antidifferentiation
  - position, from velocity, from acceleration
- Arclength
